$\begin{array}{c} Problem \ Set \ \#8 \\ {\tt CHEM101A: \ General \ College \ Chemistry} \end{array}$

Donald Aingworth IV October 10, 2025

Using the enthalpies of formation in T1: Standard Thermodynamic Quantities of your online textbook, calculate the amount of heat that will be released when 5.00 g of solid NaNO₃ reacts with excess graphite in an open container. The chemical equation for this reaction is:

$$4 \text{ NaNO}_3(s) + 5 \text{ C(s, graphite)} \longrightarrow 2 \text{ Na}_2 \text{O(s)} + 2 \text{ N}_2(g) + 5 \text{ CO}_2(g)$$

23.1 Solution

We can divide this reaction into two separate parts: the decomposition of the NaNO₃ and the recomposition of Na₂O and CO₂.

$$NaNO_3(s) \longrightarrow Na(s) + \frac{1}{2}N_2(g) + \frac{3}{2}O_2(g), \Delta H = 467.9 \text{ kJ/mol}$$
 (1)

$$2 \operatorname{Na(s)} + \frac{1}{2} \operatorname{O_2(g)} \longrightarrow \operatorname{Na_2O(s)}, \Delta H = -414.2 \text{ kJ/mol}$$
 (2)

$$C(s, graphite) + O_2(g) \longrightarrow CO_2(g), \Delta H = -393.5 \text{ kJ/mol}$$
 (3)

Multiply the first by four, the second by two, and the third by five.

$$4 \text{ NaNO}_3(s) \longrightarrow 4 \text{ Na}(s) + 2 \text{ N}_2(g) + 6 \text{ O}_2(g), \Delta H = 1871.6 \text{ kJ/mol}$$
 (4)

$$4 \operatorname{Na(s)} + \operatorname{O_2(g)} \longrightarrow 2 \operatorname{Na_2O(s)}, \Delta H = -828.4 \text{ kJ/mol}$$
 (5)

$$5 \text{ C(s, graphite)} + 5 \text{ O}_2(\text{g}) \longrightarrow 5 \text{ CO}_2(\text{g}), \Delta \text{H} = -1967.5 \text{ kJ/mol}$$
 (6)

Add all of these together. for the sake of simplification, I will denote the cancelations out early.

$$4 \text{ NaNO}_3(s) \longrightarrow 4 Na(s) + 2 N_2(g) + 6 O_2(g), \Delta H = 1871.6 \text{ kJ/mol}$$
 (7)

$$4Na(s) + O_2(g) \longrightarrow 2Na_2O(s), \Delta H = -828.4 \text{ kJ/mol}$$
 (8)

$$5 \text{ C(s, graphite)} + 5Q_2(g) \longrightarrow 5 \text{ CO}_2(g), \Delta H = -1967.5 \text{ kJ/mol}$$
 (9)

$$4 \text{ NaNO}_3(s) + 5 \text{ C(s, graphite)} \longrightarrow 2 \text{ Na}_2 \text{O(s)} + 2 \text{ N}_2(g) + 5 \text{ CO}_2(g)$$
 (10)

The total enthalpy would be the sum of all enthalpies.

$$\Delta H = \Delta H_1 + \Delta H_2 + \Delta H_3 = -924.3 \,\text{kJ/mol} \tag{11}$$

Now convert the 5 grams of solid NaNO₃ to moles.

$$MM(\text{NaNO}_3) = 22.99 + 14.01 + 48.00 = 85.00 \,\text{g/mol}$$
 (12)

$$n(\text{NaNO}_3) = \frac{m}{MM} = \frac{5.00 \,\text{gram}}{85.00 \,\text{g/mol}} = 0.0588 \,\text{mol}$$
 (13)

Multiply this by the enthalpy to find the heat.

$$Q = \frac{n * \Delta H}{n_{\text{NaNO}_3}} = \frac{0.0588 \,\text{mol} * (-924.3 \,\text{kJ/mol})}{4} = -13.6 \,\text{kJ} \tag{14}$$

Since it's negative, that means it releases 13.6 kJ.

Pyrrole (C_4H_5N) is a liquid that reacts with oxygen as follows:

$$4\,C_{4}H_{5}N\left(l\right)+21\,O_{2}(g) \longrightarrow 16\,CO_{2}(g)+10\,H_{2}O\left(l\right)+2\,N_{2}(g), \Delta H=-9407\,kJ$$

Using this information and the enthalpies of formation in **T1: Standard Thermodynamic Quantities** of your online textbook, calculate the enthalpy of formation (ΔH_f°) of $C_4H_5N(l)$.

For the reaction $4 \, \mathrm{K(s)} + \mathrm{O_2(g)} \longrightarrow 2 \, \mathrm{K_2O(s)}, \Delta H = -722 \, \mathrm{kJ}$. Using this information, calculate ΔH for each of the following three reactions.

- $a) \ 12\,\mathrm{K}(\mathrm{s}) + 3\,\mathrm{O}_2(\mathrm{g}) \longrightarrow 6\,\mathrm{K}_2\mathrm{O}(\mathrm{s})$
- b) $K(s) + \frac{1}{4}O_2(g) \longrightarrow \frac{1}{2}K_2O(s)$
- c) $12 \,\mathrm{K}_2\mathrm{O}(\mathrm{s}) \longrightarrow 24 \,\mathrm{K}(\mathrm{s}) + 6 \,\mathrm{O}_2(\mathrm{g})$

Given the following chemical reactions and ΔH values:

$$\begin{array}{ll} 3\,\mathrm{Ag^+(aq)} + \mathrm{PO_4}^{3-}(\mathrm{aq}) \longrightarrow \mathrm{Ag_3PO_4(s)} & \Delta\mathrm{H} = -32.7\,\mathrm{kJ} \\ \mathrm{Ag^+(aq)} + \mathrm{Cl^-(aq)} \longrightarrow \mathrm{AgCl}\,(\mathrm{s}) & \Delta\mathrm{H} = -65.5\,\mathrm{kJ} \end{array}$$

Calculate ΔH for the chemical reaction below:

$$Ag_3PO_4(s) + 3\operatorname{Cl}^- \longrightarrow 3\operatorname{AgCl}(s) + PO_4{}^{3-}(aq)$$

Given the following chemical reactions and ΔH values:

$$\begin{split} As_2O_5(s) + 3\,H_2O\left(l\right) &\longrightarrow 2\,H_3AsO_4(s) \\ H_3AsO_4(s) + 3\,KOH\left(s\right) &\longrightarrow K_3AsO_4(s) + 3\,H_2O\left(l\right) \\ 2\,KOH\left(s\right) &\longrightarrow K_2O\left(s\right) + H_2O\left(l\right) \\ \Delta H &= -31.6\,kJ \\ \Delta H &= 202.0\,kJ \end{split}$$

Calculate ΔH for the chemical reaction below:

$$As_2O_5(s) + 3 K_2O(s) \longrightarrow 2 K_3AsO_4(s)$$

The enthalpy of fusion (ΔH_f°) of solid AgNO₃ is -124 kJ/mol.

- a) Based on this information, write a balanced chemical equation for which $\Delta H=$ -124 kJ. Include the state of each substance in your equation.
- b) Write a balanced chemical equation for which $\Delta H = 124$ kJ.
- c) Write a balanced chemical equation for which $\Delta H = -62$ kJ. Hint: 124 = 2 $\times 62.$

The enthalpy of formation of solid AgBr is -100.4 kJ. Based on this information, can you calculate ΔH for the reaction $Ag^+(aq) + Br^-(aq) \longrightarrow AgBr(s)$? Explain why or why not.

Calculate the volume of gaseous C_4H_{10} (butane) at 25.00°C and 785.0 torr that must be burned in a closed, rigid container if you want to obtain enough heat to convert 15.50 g of ice at 0.00°C into steam at 100.00°C. Use the following information:

```
\begin{array}{l} \Delta H_f^\circ \ of \ C_4 H_{10}(g) = -149.1 \ kJ/mol \\ \Delta H_f^\circ \ of \ H_2 O (l) = -285.8 \ kJ/mol \\ \Delta H_f^\circ \ of \ CO_2(g) = -393.5 \ kJ/mol \\ \Delta H_{fusion} \ of \ ice = 6.009 \ kJ/mol \\ \Delta H_{vaporization} \ of \ water = 40.67 \ kJ/mol \ at \ 100^\circ C \\ Average \ specific \ heat \ capacity \ of \ liquid \ water \ in \ the \ range \ 0^\circ C \ to \ 100^\circ C = 4.174 \\ \frac{J}{g.^\circ C}. \ Do \ not \ look \ up \ any \ other \ thermochemical \ information. \end{array}
```

Calculate the following properties of light that has a wavelength of 490 nm.

- a) The frequency
- b) The energy of one photon, in joules
- c) The photon energy in kJ/mol
- d) The number of moles of photons required to supply 10.0 kJ of energy
- e) The total energy of 0.0125 moles of photons
- f) The number of individual photons required to supply 25.0 J of energy.

Frequencies of FM radio stations are usually given in megahertz (MHz), where 1 MHz equals $106~{\rm sec^{-1}}$. For a radio station that broadcasts at 94.3 MHz, calculate the following:

- a) The frequency in \sec^{-1}
- b) The wavelength of the radiation, in meters
- c) The wavelength of the radiation, in nanometers
- d) The photon energy, in joules
- e) The photon energy, in kJ/mol

Molecular bromine (Br₂) breaks apart into bromine atoms if it is exposed to light whose energy is 190 kJ/mol.

- a) Calculate the wavelength of this light, in nanometers.
- b) Does this light fall in the visible spectrum? If not, does it fall in the infrared region, or in the ultraviolet region?

When an atom absorbs light, does an electron in the atom move from a lower energy level to a higher energy level, or does it move from a higher level to a lower level?

Here are two of the allowed energy levels for a lithium atom:

Level 2:
$$-8.638 \times 10^{-19} \text{ J}$$
; Level 3: $-5.678 \times 10^{-19} \text{ J}$

- 1. What is ΔE for a lithium atom when an electron moves from level 3 to level 2? Give your answer in joules.
- 2. What is ΔE for a lithium atom when an electron moves from level 2 to level 3? Give your answer in joules.
- 3. Convert your answer to part a into kJ/mol.
- 4. When the electron drops from level 3 to level 2, the atom emits a photon. Calculate the wavelength of this photon, in nanometers.
- 5. Can visible light move an electron from level 2 to level 3? Explain your answer.

An atom can only undergo one electron transition at a time. However, when we observe the emission spectrum of an element, we see many lines. Explain.

Here are three of the allowed energy levels for a calcium atom:

Level A: -710.3 kJ/mol; Level B: -648.4 kJ/mol; Level C: -514.2 kJ/mol

Calculate the wavelengths of the three emission lines that can be produced by electron transitions involving these levels, and list the initial and final level for each emission line.

A line in the emission spectrum of neon has a wavelength of 471.5 nm. The final energy level for the corresponding electron transition is -266.7 kJ/mol. What is the initial energy level for this transition?

The following electronic transitions and the corresponding wavelengths can be seen in the emission spectrum of potassium:

```
\begin{array}{ll} \mbox{level } 7 \rightarrow \mbox{level } 6 & \mbox{wavelength} = 770.1 \mbox{ nm} \\ \mbox{level } 8 \rightarrow \mbox{level } 7 & \mbox{wavelength} = 1243.6 \mbox{ nm} \\ \mbox{level } 10 \rightarrow \mbox{level } 8 & \mbox{wavelength} = 14,818.5 \mbox{ nm} \\ \end{array}
```

Using this information, calculate the wavelength that corresponds to the level $10 \rightarrow$ level 6 transition in a potassium atom.
